Abstract

Cloud computing provides computing power and resources as a service to users across the globe. This scheme was introduced as a means to an end for customer’s worldwide, providing high performance at a cheaper cost when compared to dedicated high-performance computing machines. This provision requires huge data-centers to be tightly-coupled with the system, the increasing use of which yields heavy consumption of energy and huge emission of CO₂. Since energy has been a prime concern of late, this issue generated the importance of green cloud computing that provides techniques and algorithms to reduce energy wastage by incorporating its reuse. In this survey we discuss key techniques to reduce the energy consumption and CO₂ emission that can cause severe health issues. We begin with a discussion on green matrices appropriate for data-centers and then throw light on green scheduling algorithms that facilitate reduction in energy consumption and CO₂ emission levels in the existing systems. At the same time the various existing architectures related to green cloud also discussed in this paper with their pros and cons.

Keywords: Green cloud computing, energy efficiency, CO₂ emission

1. Introduction

According to Wikipedia [wiki], Cloud computing is a collection of a variety of computing concepts in which thousands of computers communicate in real-time to provide a seamless experience to the user, as if he/she is using a single huge resource. This system provides multiple facilities like – web data stores, huge computing resources, data processing servers etc. The concept of cloud computing is around since the early 1950s, although the term was not coined back then. Time sharing systems was how it was addressed back then. During the period of 1960-1990, a host of experts did hint the era of cloud computing in their books or quotes. The term dumb terminal attached to the mainframes was more famous in this period, in-lieu of the term cloud computing. In the early 1990s, even the telecommunications companies began offering VPNs (Virtual Private Networks) instead of dedicated connections, which were decent in QoS but were comparatively cheaper. In 1999, Salesforce.com was among one of the first to provide enterprise applications via a website. This move aided the advent of cloud computing which was introduced around 2002 by Amazon, the organization which can be considered as one of the pioneers in the field with their Amazon Web Services (AWS) and Elastic Compute Cloud (EC2). Since 2009, after the introduction of web 2.0, other big shots in the web industry viz. Google, Yahoo etc. have also joined the club.
Cloud computing can be considered as a hierarchy of concepts, which comprises of several models. The first model is the Service Model [11] which further includes three models namely – software as a service, platform as a service and infrastructure as a service. Second is the Deployment model [11] which further comprises of public cloud, private cloud, community cloud and hybrid cloud.

According to National Institute of Standards and Technology (NIST) – “the major objective of cloud computing is to maximize the shared resources and at the same time the disadvantage is its high infrastructure cost and unnecessary power consumption.”

According to National Institute of Standards and Technology (NIST) – “the major objective of cloud computing is to maximize the shared resources and at the same time the disadvantage is its high infrastructure cost and unnecessary power consumption.”

Global warming has been a big concern of late, with high power consumption and CO₂ emission acting as a catalyst to increase the same. The world has become highly protective about the environment with inputs from contributors such as – Greenpeace, Environmental Protection Agency (EPA) of the United States and the Climate Savers Computing Initiative to name a few. With the continuously increasing popularity and usage of cloud computing and the increasing awareness of the people across the globe towards the use of eco-friendly resources has forced the researchers to devise concepts towards an eco-friendly energy efficient flavour of cloud computing called green cloud computing. According to the previous works green cloud computing facilitates the reduction of power consumption and CO₂ emission along with the reutilization of energy in an efficient way.

Cloud uses thousands of data-centers in order to process the user queries and to run these data-centers bulk amount of power is used for cooling and other processes. Every year this power consumption is gradually increasing and green cloud computing endeavours to reduce the same thus playing a helpful role to curb these issues. There are various techniques and algorithms used to minimize this expenditure [13]. Among various avenues, one area of research focuses on reduction in energy consumption by
computer servers [11], whereas the other lays stress on dynamic cluster server configuration [20, 21] to reduce the total power consumption by balancing load and effectively utilizing only a subset of the resources at hand. Similarly Dynamic CPU clock frequency scaling [22, 23] again incorporates some form of load balancing to save power during different load conditions. In addition to these, some more techniques are used to measure the power consumption in data-centers. The first one was developed by the Green Grid called Power Usage Effectiveness (PUE) metric to measure the effectiveness of data centers. PUE tells about the amount of extra power required for cooling IT equipment [16].

It is clear from Figure 1 that in cloud scenario power consumption is very high with high carbon emission whereas at the same time in green cloud this is very less as compared to traditional cloud. Green clouds avoid power wastage and this is the reason for adoption of this technology by IT companies like Google, Microsoft, Yahoo!, etc. According to a survey done in the year 2007 IT industries contribute to 2% of the total carbon emission every year [19]. European Union (EU) is also of the view that severe reductions of the order of 15%-30% is required to maintain the global temperature and stop it from increasing drastically before 2020 [19].

The remainder of this article is organized as follows. Section II reviews previous research in the field of green cloud computing. In Section III we briefly describe the approach used to address the problem. Section IV examines the proposed work with the existing method. Finally, we summarize the study and give way for future research in Section V.

2. Existing Work

The use of Green Cloud Computing has increased substantially in the recent past. A lot of research has been done to incorporate and enhance the applicability of Green Cloud in real life scenarios with these help of various parameters. Usage of energy is dramatically increases in data centers. Cavdar et al., [1,2] introduced for improving the energy efficiency of the running data centers, the Green grid is proposing some parameters like Power Usage Effectiveness (PUE) [7] and Data centre Efficiency (DCE) metrics [10], TDP (Thermal Design Power) [2], etc. PUE is the common parameter.

According to Wikipedia “PUE is a measure of how efficiently a computer datacenter uses its power “The range of PUE is varies from 1.0 to infinity. If the value of PUE approaching 1.0 it means efficiency is 100% and full power is used by IT equipment’s. In recent years some companies achieved low PUE levels, like Google PUE with 1.13 [9]. If the value of PUE is 1.5 it means that energy consumed by IT equipment in 1kWh, by data centre 1.5 kWh and 0.5 WH energy has wasted as fruitless work like cooling, CPU dissipation and other work. Table I explain some parameters proposed for data centers. In many data centre the value of PUE reached to 3.0 or more but by using correct design 1.6 values should be achievable [5]. This calculation is done in Lawrence Berkley National Labs [8] which illustrate that 22 data centers 22 datacenters measured had PUE values in the 1.3 to 3.0 range [8].

Truong Duy, Sato and Inoguchi et al., [3] implement the green scheduling algorithm combines with neural network predictor for reducing the energy consumption in cloud computing. In this algorithm, the server predicts the load from time t to the time it takes for restarting and calculates the peak load. According to the peak load the number of server state is decided. Let, N₀ is the number of server in ON state and Nₙ is the number of necessary
servers. If the $N_n > N_o$ then, choose server in OFF state, signal them to restart and if $N_n < N_o$ choose server in ON state and signal them to shut down.

Fumiko Satoh et al., [4] also focus on reducing the usage of energy in data centers. But for the future energy management they develop an energy management System for cloud by the use of sensor management function with an optimized VM allocation tool. This system will help to reduce the energy consumption in multiple data centers and results shows that it will save 30% of energy. This system also used to reduce the energy in carbon emissions.

**Table 1. Green metrics power measurement [1, 2]**

<table>
<thead>
<tr>
<th>Metric</th>
<th>Explanation</th>
<th>Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>Power usage effectiveness (PUE)</td>
<td>It is the fraction of total energy consumed by the service of a data centre to the total energy consumed by IT equipments.</td>
<td>$PUE = \frac{\text{Total facility energy}}{\text{IT equipment energy}}$</td>
</tr>
<tr>
<td>Carbon Usage Effectiveness (CUE)</td>
<td>It is a calculation of greenhouse gases (CO2, CH4) release in atmosphere by the data centre.</td>
<td>$\text{CUE} = \frac{(\text{Total CO2 emission from total energy used for service of data centre})}{\text{Total energy consumed by IT equipment}}$</td>
</tr>
<tr>
<td>Water Usage Effectiveness (WUE)</td>
<td>It is calculation of yearly water used by data centre like for cooling, energy Production.</td>
<td>$\text{WUE} = \frac{\text{Annual usage of water}}{\text{Total energy used by IT equipment}}$</td>
</tr>
<tr>
<td>Energy Reuse Factor (ERF)</td>
<td>It calculates the reusable energy Like hydro power, solar power etc used by data center.</td>
<td>$\text{ERF} = \frac{\text{used of reused energy}}{\text{Total energy used by IT equipment}}$</td>
</tr>
<tr>
<td>Energy Reuse Effectiveness (ERE)</td>
<td>It is a parameter for measuring the profit of reuse energy from a data centre.</td>
<td>$\text{ERE} = \frac{\text{Total energy - reused energy}}{\text{Total energy used by IT equipment}}$</td>
</tr>
<tr>
<td>Data centre Infrastructure Efficiency (DCiE)</td>
<td>This factor is used to calculate The energy efficiency of a data Centre.</td>
<td>$\text{DCiE} = \frac{\text{Total IT equipment power}}{\text{Total facility power}} \times 100%$</td>
</tr>
<tr>
<td>Data Centre Productivity (DCP)</td>
<td>It calculates the amount of useful work done by data centre.</td>
<td>$\text{DCP} = \frac{\text{Total Useful work}}{\text{Total resource used to do this work}}$</td>
</tr>
<tr>
<td>Compute Power Efficiency (CPE)</td>
<td>It determines the total amount of power is truly used for computing.</td>
<td>$\text{CPE} = \frac{\text{IT equipment utilization energy}}{\text{PUE}}$</td>
</tr>
</tbody>
</table>
Green Energy coefficient (GEC)

It measures the amount of green energy used to provide services to a data center.

\[
GEC = \frac{\text{Green energy consumed}}{\text{Total energy consumed}}
\]

Space, Wattage and Performance (SWaP)

It is used for work out the space and energy required by the data center.

\[
\text{SWaP} = \frac{\text{Performance}}{\text{Space} \times \text{power}}
\]

DataCentre Energy Productivity (DCEP)

It calculates the quantity of useful work done by the data center as compared to total energy consumed to make this work.

\[
\text{DCEP} = \frac{\text{Total useful work done}}{\text{Total energy used to do this work}}
\]

Cooling is another major issue that consumes huge amounts of energy in data centers. Previously, the cooling is done by using mechanical refrigerators that supply chilled water for the IT equipment. Now a day’s pre-cooling is also called as free cooling is used. Free cooling minimizes the use of mechanical cooling. Like Facebook deploys their data center in Sweden which has cold and dry climate. Microsoft leaves servers in open air in order to cool the servers easily. Also Google uses river water to cool their data center [1]. There are different hardware technologies like virtualization and software technologies like software efficient algorithms used to decrease the consumption of energy.

Rasoul Beik et al., [6] proposes an energy aware layer in software –architecture that calculates the energy consumption in data centers and provides services to the users which uses energy efficiently. Bhanu Priya et al., [11] gave a cloud computing metrics to make the cloud green in terms of energy efficiency, different energy models have been discussed in this paper to reduce the power consumption and CO2 emission to make cloud more green. This survey takes three major factors under consideration; any cloud can be green by following these factors, first cause to make cloud greener is virtualization, second is Work load distribution and third is software automation, some other factors are also discussed like pay-per-use and self-service which is proved as a key for reduction of energy consumption.

According to Kliazovich and Pascal Bouvry [12] expenses on cloud data centers maintenance and operation done in cloud are gradually increasing. In this paper author has focused on the work load distribution among the data centers so that energy consumption can be calculated in terms of packet level. By this technique packet level communication is achieved. Packet level simulation of energy has been done through the simulator, like for green cloud NS2 simulator and for cloud only one existing called “cloudsim”. This simulation is done at three levels: “two-tier, three-tier, and three-tier high-speed data center architectures”. Kaur and Singh et al., [13] performed the different challenges in the field of energy in cloud computing, a model is proposed by the author to calculate the energy wasted by producing various gases in the environment. The proposed model contains various fields Data, Analysis, Record, Put on guard, restrain along with the virtualization concept in green cloud to make it energy efficient and for healthy environment.

Hosman and Baikie et al., [14] gave a new challenge in the field of cloud computing, datacenters consumes a lot of energy and energy is available every time is not necessary, so the author is discussing in his paper about the solar energy. How the solar
energy can play a vital role in data centers energy consumption is the hot topic of
discussion. In this paper author proposed a small level cloud data center which is the
combination of three technologies are “less power consumption platform, energy
efficient cloud computing and DC power distribution”. Owusu et al., [17] performed a
survey to establish the current state of the art in the area of energy efficiency in cloud
computing. They beautifully mention the field of energy efficiency as a controversial
area to cloud computing. This paper discusses one area of controversy; the energy
efficiency of cloud computing.

Yamini et al., [18] Introducing the key approaches like virtualization, Power
Management, Recycling of material and telecommuting of green cloud computing very
beautifully. The major focus of this paper is the consolidation or scheduling of task and
resource utilization in green cloud computing to reduce the high consumption of
energy. The decent results shown in the paper not for the direct drastic energy reduction
but applies possible saving of electricity in huge cloud data centers. According to
Buyya [19] the demand of cloud is drastically increasing now a day and the
consumption of energy and excretion of harmful gases is also extreme which is very
harmful and a big issue in the field of health care and also a big reason of the increase
in cost of operations in cloud. Buyya gave a presentable and evidential literature survey
of the various different members of cloud which participate in the total energy
consumption. Structure of cloud are discussed in this paper which turn on the use of
green cloud computing.

Buyya et al., [24] contributes carbon green cloud architecture which points on the
third party concept, consist of two types of directories named as green offer and carbon
emission. These directories help us to provide and utilize the Green services from users
and providers both. Green brokers access the services from green offers directory and
scheduled services according to least CO2 emission. Beloglazov and Buyya et al., [25]
focuses on virtual machine for the reduction of the energy consumption. An author
proposes the dynamic reallocation technique for VMs and toggles off the unused
servers which results, considerable energy saving in the real Cloud Computing data
centers.

Nimje et al., [28] addressed the security of the cloud data centres in order to achieve
green cloud environment by using virtualization concept. Various methods are involved
in the paper to address the security and reduction of power consumption. Virtualization
here came in to picture because it reduces the load from the data centres and provides
deployment, management and delivery of resources in simple manner. Nimje included
hypervisor environment to provide the virtualization and works as a security tool to
achieve high level of security in green cloud computing.

3. Existing Approaches

Buyya et al., [24] contributes carbon green cloud architecture which points on the third
party concept, consist of two types of directories named as green offer and carbon emission.
These directories help us to provide and utilize the Green services from users and providers
both.

The services of the providers are registered in the “Green offer Directory”. The Green
Broker accessed these services and organized it according to the price, time and the service
that offer least CO2 emission. The Carbon Emission Directory keeps and stores the data
which contains the information of energy and cooling efficiency of cloud services and data
centers. The green broker used the up to date information about services.
Whenever the user requests for the services, it contacts with the Green Broker. The Green Broker uses these directories and chooses the green offer and energy efficiency information and allocates the services to the private cloud. And finally, give the result to the users. This directory idea is beautifully used by the Hulkury *et al.*, [26] and Garg *et al.*, [27] and proposes a new architecture called as integrated green Cloud architecture (IGCA) shown in Figure 2. It smartly includes client oriented in the Cloud Middleware that verifies the cloud computing is better than the local computing with QoS and budget.

![Figure 2. Integrated green Cloud architecture (IGCA) [26]](image)

This architecture has two elements; one is the client and second is the server side. In the client side the manager and the users are present, which deals with the execution destination of the job and in the server side includes the green cloud middleware, green broker and sub servers like processing servers, storage servers etc. The directory concept is used in the green broker layer of IGCA for organizing all the information of the public cloud and provides the best green service to the user.

The green cloud middleware has two components. The manager is the main head that deals with one component and stores all the information of the middleware. The usage of the user’s PC, the servers present on the private clouds all the information. The frequencies of each sever like high, medium and low. The energy usage, storage capacity [26] and other information also exist in the component of middleware.

When the manager got request from the client. The request is dividing into jobs and distributed among the users meanwhile they also stores the information about job into the component. The carbon emission and energy used for the execution of job on the private cloud by servers, on the public cloud by using green broker or on the client’s PC is calculated and show to the users. The best green offer is selected by the manager by taking into consideration the security level of the job also. When the decision is making out by the manager then this information is store in the XML file for future usage.

The second component is accessed by all the users for reading the XML file. This file stocks all the information of the execution of job. The locations of the jobs are registered in
the file and according to the addresses, they will execute. If the job entry is not in the file then
the job will be executed either on the PC of the client or in the private cloud. The execution of
job is takes place in three places. First if the job is executed LOCALLY (on the requester
side) then this information is stored in the client side so next time when the request arrives it
will not get through will middleware. If the job is executed in the private cloud the location as
well as the server name is fetched from the file. Or if it is in public cloud, we will take help
from the green broker to know the most excellent green decision for the execution of the job.
The middleware know all the information about the three places. Energy used by the workers
working in the company is also calculated by the middleware for taking further decisions.

The processing speed, energy consumption, bandwidth or others factors are responsible for
deciding the best location for the execution of the job. By considering all the factors the
middleware will compute and judge the place from the three places. The IGCA provides the
balance in the job execution and provide the security and quality of service to the clients. The
manager divides the task and top quality green solution by considering all the places (public,
private, local host).

In this architecture the manager plays the central coordinator work which allocates the job
to the users and does all decision making. But at the same time the manager is the weakest
point in this architecture as it is the central point of failure, as if the manager fails everything
in the architecture collapses.

4. Advantages and Disadvantages

As we have discussed above that all existing architectures have some constructive as well
as destructive points. Buya et al., [19] gave the architecture for green cloud the major
advantage of this architecture is Co2 emission directory, this directory measures the best
suitable service which gives less carbon emission so straight away it indicates that energy will
also decrease because Co2 emission and energy consumption both are directly proportionate
to each other. Similarly the disadvantage is that only CO2 emission and energy is not the
factor to be under consideration like Quality Provisioning, Security, etc.

Hulkary et al., [26] covers these factors also under consideration by taking other
components which search service first on the private cloud later on public cloud this reduces
the time consumption and provides better results as compare to Buya Architecture. The major
disadvantage which we observed here is that manager of the system is the central point of
communication so if manager will crash then whole system will fall apart at the same time
decision making done by manager is not intelligent and all work has been done manually.

These are the some of the advantages and disadvantages which observed here in these
existing architectures and which can be further improve for the future work.

5. Conclusions and Future Work

In this paper we addressed the problem of traditional cloud and the use of green
cloud at the same time we enlighten the recent work which has been done in the field of
green cloud computer for healthy and greener environment. Consequently we gave a
comparative study in the field of green cloud computing. There are many possible
directions of future work. While in the paper we address the problem of efficient way to
fetch the results from the cloud so all the features covered in the paper can be achieved.
Further we can implement the approach to automate the manager of the green cloud
who makes all the decisions regarding the services.
